#### BACKGROUND OF THE INVENTION

The present application relates generally to slew rate control circuitry, and more specifically to circuitry for controlling the slew rate of switched power supplies.

Slew rate control circuitry is frequently employed in conjunction with switched power supplies. For example, the slew rate of a switched power supply on a mother printed circuit (PC) card is often controlled to limit the in-rush current charging bulk decoupling

ATTORNEY DOCKET NO. TI-36859 (UNITI-173XX) WEINGARTEN, SCHURGIN, GAGNEBIN & LEBOVICI LLP TEL. (617) 542-2290 FAX. (617) 451-0313

EXPRESS MAIL NUMBER

capacitors on one or more daughter PC cards. Such slew rate control of the mother PC card power supply is necessary because excessive in-rush current can (1) adversely affect the operation of the switched power supply, (2) trigger unwanted system resets, and/or (3) disrupt system processor operation.

A conventional approach for controlling the slew rate of a switched power supply employs a source-follower circuit configuration, in which a capacitor is connected to the gate of a Field Effect Transistor (FET), an input supply voltage is connected to the drain of the FET, and an output supply voltage is provided across a load connected to the source of the FET. The capacitor is charged by a constant current to provide a linear voltage ramp to the gate of the FET. Because the voltage on the source of the FET follows the linear voltage ramp on the gate of the FET, slew rate control of the output supply voltage is achieved. In the event it is desired to control the slew rate of a positive output voltage, the source-follower typically includes an NMOS In the event the slew rate of a negative output supply voltage is to be controlled, the source-follower typically includes a PMOS FET.

Although the conventional source-follower circuit described configuration above has been successfully employed to control the slew rate of switched power supplies, the source-follower approach has For example, the source-follower requires a drawbacks. charging capacitor, which can be bulky and expensive.

5

10

15

20

Further, when controlling the slew rate of a negative output supply voltage, the source-follower requires a PMOS FET, which can also be an expensive circuit component.

Instead of using a PMOS FET to control the slew rate the negative output supply, FET may be an NMOS employed. For example, another conventional circuit configuration has the negative input supply connected to the source of the NMOS FET, the negative output supply voltage provided across a load connected to drain of the NMOS FET, and a Miller capacitor connected between the gate and the drain of the NMOS FET. As in the conventional source-follower circuit configuration, a constant current source is used to charge the Miller capacitor. However, this alternative circuit configuration also has drawbacks due at least in part to the bulky and expensive Miller capacitor.

It would therefore be desirable to have circuitry for controlling the slew rate of switched power supplies that avoids the drawbacks of the above-described circuit configurations.

#### BRIEF SUMMARY OF THE INVENTION

In accordance with the present invention, circuitry is provided for controlling the slew rate of a negative output supply that requires neither an external capacitor nor a PMOS FET and therefore has reduced cost. Benefits of the presently disclosed slew rate control circuitry are achieved by employing an NMOS FET in a closed loop

5

10

15

circuit configuration, in which the slew rate of the negative output supply linearly tracks the slew rate of a master positive output supply.

In one embodiment, the slew rate control circuitry includes an NMOS FET, a feedback resistor having first and second terminals connected between the drain and the gate of the NMOS FET, the first terminal of the feedback resistor being connected to the drain of the NMOS FET, an input resistor connected to the second terminal of the feedback resistor, level shifting circuitry connected between the positive output supply voltage and the input resistor, and a bias current source connected to the gate of the NMOS FET. Further, a negative input supply voltage is connected to the source of the NMOS FET, and the negative output supply voltage is provided across a load connected to the drain of the NMOS FET.

In the presently disclosed embodiment, the master positive supply voltage is controlled to ramp from 0 to  $+V_S$  volts. As the positive supply voltage ramps from 0 to  $+V_S$ , the level shifter provides a voltage to the input resistor that ramps from  $-V_S$  to 0 volts. Because the gate voltage of the NMOS FET remains substantially constant as the voltage applied to the input resistor ramps from  $-V_S$  to 0 volts, the drain voltage of the NMOS FET ramps from 0 to  $-V_S$ , thereby providing a negative output supply voltage  $-V_S$  with a slew rate that linearly tracks the slew rate of the master positive output supply. The level of the bias current source is selected so that the level of the node between the input resistor and the feedback

5

10

15

20

resistor is within the normal active operating region of the NMOS FET.

Because of the closed loop circuit formed by the NMOS FET and the feedback resistor, the presently disclosed slew rate control circuitry provides a negative output supply with a slew rate that linearly tracks the slew rate of a master positive output supply.

Other features, functions, and aspects of the invention will be evident from the Detailed Description of the Invention that follows.

### BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

The invention will be more fully understood with reference to the following Detailed Description of the Invention in conjunction with the drawings of which:

- Fig. 1 is a schematic diagram of a first conventional slew rate control circuit configuration;
- Fig. 2 is a schematic diagram of a second conventional slew rate control circuit configuration;
- Fig. 3 is a schematic diagram of circuitry for controlling the slew rate of a negative output supply according to the present invention;
  - Fig. 4 is a detailed schematic diagram of the slew rate control circuitry of Fig. 3; and
- 25 Fig. 5 is a schematic diagram of an alternative embodiment of the slew rate control circuitry of Fig. 4.

#### DETAILED DESCRIPTION OF THE INVENTION

U.S. Provisional Patent Application No. 60/501,006 filed September 8, 2003 Attorney Docket No. TI-36859 (UNITI-173XX) entitled LINEAR VOLTAGE TRACKING AMPLIFIER FOR NEGATIVE SUPPLY SLEW RATE CONTROL is incorporated herein by reference.

Circuitry is disclosed for controlling the slew rate of a negative output supply. The presently disclosed slew rate control circuitry includes a closed loop circuit configuration that allows the slew rate of the negative output supply to linearly track the slew rate of a master positive output supply.

depicts conventional circuitry 100 controlling the slew rate of a positive output supply. As shown in Fig. 1, the conventional slew rate control circuitry 100 employs source-follower а circuit configuration including an NMOS Field Effect Transistor (FET)  $M_1$ , a constant current source  $I_{s1}$ , a gate capacitor  $C_q$ , and a load resistor  $R_L$ . The capacitor  $C_q$  is connected between the gate of the NMOS transistor  $M_1$  and ground, a constant positive input supply voltage  $+V_{sin}$  (e.g.,  $+V_{sin}$  = volts) is connected to the drain of the transistor  $M_1$ , and a positive output supply voltage  $+V_{Sout}$ (e.g.,  $+V_{sout} = +12$  volts) is provided across the load resistor R<sub>L</sub> connected between the source of The current source  $I_{S1}$  provides transistor  $M_1$  and ground. a constant current to charge the capacitor  $C_q$ , thereby providing a linear voltage ramp to the gate of the NMOS transistor  $M_1$ . Slew rate control of the positive output

5

10

15

20

supply is achieved because the positive output voltage  $+V_{\text{Sout}}$  on the source of the NMOS transistor  $M_1$  follows the linear voltage ramp on the gate of the transistor  $M_1$ .

Those of ordinary skill in this art will appreciate that a source-follower circuit analogous to the slew rate control circuitry 100 for controlling the slew rate of a negative output supply typically includes at least one PMOS transistor (not shown). Such conventional source-follower circuit configurations have drawbacks, however, due at least in part to the bulky and expensive external capacitors and costly PMOS transistors.

depicts conventional circuitry 200 controlling the slew rate of a negative output supply. As shown in Fig. 2, the conventional slew rate control circuitry 200 includes an NMOS transistor  $M_2$ , a constant current source  $I_{S2}$ , a Miller capacitor  $C_M$ , and a load resistor  $R_L$ . The Miller capacitor  $C_M$  is connected between the gate and the drain of the NMOS transistor  $M_2$ , constant negative input supply voltage  $-V_{sin}$  (e.g.,  $-V_{sin}$  = volts) is connected to the source of the transistor  $M_2$ , and a negative output supply voltage  $-V_{\text{Sout}}$ (e.g.,  $-V_{\text{Sout}} = -12 \text{ volts}$ ) is provided across the resistor R<sub>L</sub> connected between the drain of transistor  $M_2$  and ground. The current source I<sub>S2</sub> provides a constant current to the gate of the NMOS transistor  $M_2$ and the Miller capacitor  $C_M$  connected thereto, thereby controlling the slew rate of the negative output supply. The conventional slew rate control circuitry 200 also has

10

15

20

drawbacks, however, due at least in part to the bulky and expensive Miller capacitor  $C_{\text{M}}$ .

Fig. 3 depicts an illustrative embodiment of circuitry 300 for controlling the slew rate of a negative output supply, in accordance with the present invention. In the illustrated embodiment, the slew rate control circuitry 300 includes an NMOS FET  $M_3$ , level shifting circuitry 302, an input resistor  $R_{\rm IN}$ , a feedback resistor  $R_{\rm F}$ , a bias current source  $I_{\rm BIAS}$ , and a load resistor  $R_{\rm L}$ . A constant negative input supply voltage  $-V_{\rm Sin}$  (e.g.,  $-V_{\rm Sin}$  = -12 volts) is connected to the source of the NMOS transistor  $M_3$ , and the negative output supply voltage  $-V_{\rm Sout}$  (e.g.,  $-V_{\rm Sout}$  = -12 volts) is provided across the load resistor  $R_{\rm L}$  connected to the drain of the transistor  $M_3$ .

As shown in Fig. 3, a positive output supply voltage  $+V_{Sout}$  (e.g.,  $+V_{Sout} = +12$  volts) is provided at a noninverting input of the level shifter 302, and a constant positive input supply voltage  $+V_{sin}$  (e.g.,  $+V_{sin} = +12$ volts) is provided at an inverting input of the level shifter 302. For example, the positive output supply voltage  $+V_{\text{sout}}$  may be generated from the positive input supply voltage  $+V_{sin}$  by the source-follower circuit 100 described above with reference to Fig. 1, or any other suitable circuit configuration. Accordingly, the positive output supply voltage applied to the shifter 302 is controlled to ramp up from 0 to  $+V_{Sout}$ volts.

Because the positive input supply voltage  $+V_{\text{Sin}}$  is provided at the inverting input of the level shifter 302,

5

10

15

20

the voltage applied to the input resistor  $R_{IN}$  (node A) ramps up from  $-V_s$  to 0 volts as the positive output supply voltage ramps up from 0 to  $+V_s$ . In the presently disclosed embodiment, the NMOS transistor  $M_3$  is biased to maintain the transistor within its active operating region, and the level at node B between the input the feedback resistor  $R_{IN}$ and resistor R<sub>F</sub> remains substantially constant at the threshold voltage of the transistor  $M_3$ , as the level at node A ramps up from  $-V_S$  to The level of the bias current source  $I_{BIAS}$  is selected to place the level at node B within the active operating region of the NMOS transistor M3. Accordingly, to maintain the substantially constant voltage level at node B, the negative output supply voltage provided at the drain of the NMOS transistor  $M_{\rm 3}$  ramps down from 0 to -V<sub>sout</sub>.

As a result, the slew rate of the negative output supply  $-V_{Sout}$  linearly tracks the slew rate of the positive output supply  $+V_{Sout}$ . In effect, the positive output supply  $+V_{Sout}$  is a "master" supply, and the slew rate of this master supply along with the closed loop gain set by the feedback resistor  $R_F$  and the input resistor  $R_{IN}$  determines the slew rate of the negative output supply  $-V_{Sout}$ .

It is noted that the slew rate control circuitry 300 provides closed loop control of the negative output supply slew rate. The output of the master positive supply is connected via the level shifter 302 to the input resistor  $R_{\text{IN}}$ , which functions as the input of a

5

10

15

negative supply slew rate control loop 304. In the presently disclosed embodiment, the control loop 304 of the negative supply slew rate comprises the feedback resistor  $R_{\text{F}}$  connected across the gate and the drain of the NMOS transistor  $M_3$ .

Fig. 4 depicts a more detailed embodiment 400 of the slew rate control circuitry 300 (see Fig. 3). In the illustrated embodiment, the slew rate control circuitry 400 comprises an NMOS FET  $M_4$ , level shifting circuitry 402, an input resistor  $R_{IN}$  (e.g.,  $R_{IN}=80~\mathrm{K}\Omega$ ), a feedback resistor  $R_F$  (e.g.,  $R_F=240~\mathrm{K}\Omega$ ), a bias current source 406, and a load resistor  $R_L$ . The constant negative input supply voltage  $-V_{Sin}$  (e.g.,  $-V_{Sin}=-12~\mathrm{volts}$ ) is connected to the source of the NMOS transistor  $M_4$ , and the negative output supply voltage  $-V_{Sout}$  (e.g.,  $-V_{Sout}=-12~\mathrm{volts}$ ) is provided across the load resistor  $R_L$  connected to the drain of the transistor  $M_4$ .

As shown in Fig. 4, the positive output supply voltage  $+V_{Sout}$  (e.g.,  $+V_{Sout} = +12$  volts) is provided at a resistor R408 (e.g., R408 = 48 K $\Omega$ ) corresponding to the non-inverting input of the level shifter 402. the constant negative input supply voltage  $-V_{sin}$  (e.g., - $V_{sin}$  = -12 volts) is provided at a resistor R410 (e.g., R410 = 40 $K\Omega$ ) of the level shifter 402, thereby representing the positive input supply voltage (e.g.,  $+V_{Sin} = +12$  volts) provided to the inverting input of the level shifter 302 of Fig. 3. As described above with reference to Fig. 3, the positive output supply is the master supply, which applies a voltage to the level

5

10

15

20

shifter 402 that is controlled to ramp up from 0 to  $+V_{\rm Sout}$ . The resistors 408 and 410 level shift this master ramp voltage from  $+V_{\rm Sout}$  to the common mode negative input supply voltage  $-V_{\rm Sin}$ .

The slew rate control circuitry 400 further comprises a negative supply slew rate control loop 404 including the feedback resistor  $R_{ extsf{F}}$  and a resistor R412 (e.g., R412 = 90 K $\Omega$ ). It is noted that current summed at the input of the negative supply slew rate control loop 404 provides a "virtual node" as a swivel point. current causes a voltage to develop across the resistor 412 to level shift the virtual node and to generate compensation for the gate-to-source voltage (Vgs) of the NMOS transistor M4, thereby assuring ratio-metric control and a first-order cancellation of process and temperature variations of Vgs. The bias current source 406 comprises an NMOS current mirror configured to generate a current  $I_{1s}$  for producing the compensating level shift voltage.

It is further noted that the NMOS transistor  $M_4$  functions as a stable single gain stage within the slew rate control circuitry 400 (see Fig. 4). Accordingly, the NMOS transistor  $M_4$  is operative to perform as a stable linear voltage tracking amplifier for controlling the slew rate of the negative output supply  $-V_{Sout}$ .

The following are representative expressions of the current  $(I_{\rm in})$  through the resistor R408, the voltage  $(V_a)$  at node A, the voltage  $(V_b)$  at node B, the current  $(I_{\rm os})$  through the resistor R414, and the current  $(I_{\rm ls})$  generated by the NMOS current mirror:

5

10

15

$$I_{in} = +12V_{out}/48k \tag{1}$$

$$V_a = I_{in}(80k||40k) = I_{in}(26.7k)$$
 (2)

$$V_b = 1.5V(165k/75k)$$
, above  $-12V_{in}$  (3)

$$I_{OS} = 1.5V/75k \tag{4}$$

 $I_{1s} = [(1.5V/75k)*165k-Vgs]/90k$  (5)

Moreover, the following are representative calculations relating to the gain and offset of the slew rate control circuitry 400:

GAIN:

5

10 
$$I_{in} = (+12V_{out})/48k$$

$$Req = (80k||40k) = 26.7k @ Va$$

$$V_{a} = (I_{in}) (Req) = (+12V_{out}) (26.7k/48k)$$

$$-V_{sout} = -(Va/80k) (240k) \Leftrightarrow$$

$$-V_{sout} = -3 (+12V_{out}) (26.7k/48k) \Leftrightarrow$$

$$-V_{sout} \approx -1.5 (+12V_{out})$$
(6)

OFFSET:

$$I_{OS} = 1.5V/75k$$

$$V_{d} = V_{c} = I_{OS}(165k)$$

$$I_{1s} = (V_{d}-Vgs)/90k \Leftrightarrow$$

$$I_{1s} = [(1.5V/75k)*165k-Vgs]/90k$$

$$V_{b} = Vgs + I_{1s}(90k) \Leftrightarrow$$

$$V_{b} = 1.5V(165k/75k)$$
(7)

Fig. 5 depicts an alternative embodiment 500 of the slew rate control circuitry 400 (see Fig. 4). In the illustrated embodiment, the slew rate control circuitry 500 comprises an NMOS FET  $M_5$ , an input resistor  $R_{\rm IN}$ , a feedback resistor  $R_{\rm F}$ , a buffer 520, a controlled bias current source 506, and control logic 530. The constant

negative input supply voltage  $-V_{\text{Sin}}$  (e.g.,  $-V_{\text{Sin}} = -12$  volts) is connected to the source of the NMOS transistor  $M_5$ , and the negative output supply voltage  $-V_{\text{Sout}}$  (e.g.,  $-V_{\text{Sout}} = -12$  volts) is provided at the drain of the transistor  $M_5$ . Moreover, a control loop 504 of the negative supply slew rate comprises the feedback resistor  $R_F$ , the buffer 520, and a switch SW1 connected between the output of the buffer 520 and the gate of the NMOS transistor  $M_5$ .

10 The operation of the switch SW1 and the bias current source 506 is controlled by the control logic 530. Specifically, when a logical high control signal applied to an Enhance input, the control logic 530 is operative to open the switch SW1 as the level of the 15 negative output supply voltage  $-V_{\mathtt{Sout}}$ ramps to. predetermined level of the negative input supply voltage  $-V_{\text{Sin}}$ , thereby disconnecting the slew rate control after the voltage ramp completes. It is noted that the slew rate control may be disconnected via the switch SW1 after 20 the voltage ramp completes and after a predetermined time delay. Three stages of current (e.g., 250 nA, 250 nA, and 1  $\mu$ A) are then applied to the gate of the NMOS transistor  $M_5$  to ramp up the gate to 0 volts controlled manner. The control logic 530 includes a 25 counter 531 operative to turn-on each current stage in predetermined increments of time, e.g., 2 msec steps.

For example, in a first step, 250 nA may be applied to the gate of the transistor  $M_5$ ; in a second step, another 250 nA may be applied to the gate of the

transistor  $M_5$ ; and, in a third step 1  $\mu$ A may be applied to the gate of the transistor  $M_5$ , thereby applying a total of 1.5  $\mu$ A to the transistor gate. In effect, the bias current source 506 in conjunction with the control logic 530 functions as an overdrive circuit that is activated after the voltage ramp completes to provide an overdrive signal to the gate of the transistor in sequenced steps. This progressive application of current to the transistor gate via the overdrive signal avoids large spikes current on the negative input supply, enhancing the NMOS transistor  $M_5$  to reduce the resistance between the drain and source (Rdson) of the transistor and thus reduce the voltage drop across negative supply interface.

It will further be appreciated by those of ordinary skill in the art that modifications to and variations of the above-described linear voltage tracking amplifier for negative supply slew rate control may be made without departing from the inventive concepts disclosed herein.

20 Accordingly, the invention should not be viewed as limited except as by the scope and spirit of the appended claims.

5
